Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

EP 0 287 545 B1

Description

The present invention relates to a versatile storage device and holder for web material in roll form, including a brake arrangement to preventing excessive material to be given out from the roll holder.

A multiple of materials intended for many different uses are retailed in roll form. Kitchen paper and toilet paper are each examples of material in roll form used on a daily basis. Petrol stations, workshops and other places of work are normally equipped with holders which carry paper or some equivalent material for cleaning or drying the hands, wiping clean petrol-cap openings or other dirty surfaces. Public toilets and similar buildings are also often equipped with paper towels in roll form.

When the web of material is paper, the web can be torn with relative ease, and the ease with which such webs can be torn is normally enhanced by the presence of perforations. In the case of webs of woven or non-woven fabrics, fibre cloth, it is necessary to provide the web with tear lines or weakenings along which the web can be torn, so that the web can be separated into pieces that are of a size suitable for the purpose intended.

When material is taken from a roll through the central cavity thereof the material, at some stage in the life of the roll, will continue to unroll freely, in the absence of a pulling force, subsequent to withdrawing a piece of the material from the roll centre. This is, of course, due to gravity, a fact which is of small comfort when a roll unwinds in this way, to leave the material in a heap on the floor.

An attempt has been made to overcome this problem with the aid of the invention disclosed in SE 8405108-5. The dispensing arrangement described in this publication is intended solely for unwinding a paper web axially from the centre cavity of a roll.

The device which prevents the paper web from falling gravitationally from the roll has the form of an angled spring-loaded arm.

With regard to roll holders which are intended for supporting rolls from which material is unwound from the outer periphery of the roll, it will be observed that the radius of the roll constitutes a lever arm which, multiplied by the weight of the downwardly hanging material web, constitutes a turning moment which is counteracted by the friction engendered between the roll bobbin and its journal(s). This is most pronounced when the roll is full and thus presents the longest lever arm. When a piece of the web is drawn from the roll, the roll will rotate and generate inertia forces which can cause the roll to unwind. This problem is accentuated in the case of heavy rolls of relatively large

diameter, such as paper rolls in public toilets and paper towel rolls in work shops for instance.

A further problem occurring with spindle-carried or bobbin carried rolls with which material is taken from the outside of the roll is that the friction in the bobbin bearing must not be so great as to cause the material web to be torn-off at inappropriate locations therealong when pulling off the web, i.e. so that excessively short lengths are obtained. This problem is particularly pronounced when the material web is perforated. If, on the other hand, the friction is too small, there is insufficient braking force to counteract the inertia forces generated by the roll as it is rotated by pulling off material from the outer roll periphery. Even when a desired length of web is torn off quickly, so that no material is left hanging from the roll to cause the aforesaid automatic unwinding of the roll, the inertia forces generated by rotation of the roll will maintain the roll in motion. The material will thus continue to unwind unhindered from the roll.

In US-A-1,676,854, upon which the pre-characterising part of independent Claim 1 is based, is described a roll material holder carrying the roll on low-friction projections and having a braking arrangement in the form of two lips ranging radially from the holder body. The material web is drawn through a slot defined by said lips. The lips terminate with a cutting edge. Some degree of friction between the material web and the lips hinders the web to be unintentionally unwound.

The object of the present invention is to provide a holder for material webs in roll form which will support the roll vertically or horizontally for internal or external unwinding of the roll material. Another object is to provide a holder which includes means for preventing the material from being unwound gravitationally or as a result of the force of inertia of the roll in rotation. A further object is to provide a roll holder intended for carrying a roll with which material is taken from the outer periphery of the roll which minimizes the risk of severing the web upon acceleration of the roll. A further object is to provide a holder into which a fresh roll can be fitted easily. These objects are achieved with a roll holder having the characteristic features set forth in the following claims.

Thus the present invention relates to a holder for carrying a thin material web in roll form comprising the features of independent Claim 1.

Additional particular embodiments of the invention are defined in dependent Claims 2 to 12.

A preferred embodiment of the invention will now be described in more detail with reference to the accompanying drawings, in which

Figure 1 is a vertical sectional view of a roll holder with the lid of the holder slightly raised and containing a horizontally positioned roll of

paper;

Figure 2 illustrates the back plate of a roll holder and a horizontally mounted roll of paper;

Figure 3 illustrates the back plate of a holder and a vertically mounted roll of paper;

Figure 4 is a vertical sectional view of a holder provided with an alternative outlet; and

Figure 5 is a vertical sectional view of a variant which has a web outlet above the paper roll.

A roll holder for supporting a roll of relatively thin material comprises a back plate 1 which is intended to be secured to a wall or like support surface. The back plate is provided with a suitable attachment means which enables a casing 2 to be connected to the back plate, said casing comprising a front wall, two side walls and a lid and being essentially open at the bottom. The attachment means preferably comprises elements which co-act with a hinge 3 such as to allow the casing 2 to be raised through 90° when inserting a paper roll 4, thereby facilitating loading of the holder.

The two vertical side edges of the back plate 1 each have extending therealong side-wall sections 5, 6, 7 which protrude outwardly at an angle to the plane of the back plate. The upper and lower pairs of sections 5 and 7 are intended to hold the roll in position laterally and act as casing guides when lowering the casing 2 subsequent to loading the holder. The side-wall sections 5, 7 may also be configured for co-action with means provided on the inside of the casing 2 in a manner to obtain a snap-lock arrangement.

The intermediate side-wall sections 6 carry roll-support shafts 8, which are intended to be inserted into the central cavity or cylindrical hole contained by the paper roll, so as to support the roll horizontally. The shafts 8 are preferably made of a thermoplastic material which presents only a small frictional force against the sleeve of the paper roll, and the length of respective shafts 8 is such as to enable a roll to be placed horizontally on the mutually opposing shafts when bending laterally outwards the side-wall sections 6, which are made of a flexible, resilient material, whereafter the shafts 8 are allowed to spring back, into the central cavity of the roll 4. Alternatively, the roll-support shafts 8 may have a telescopic construction which includes a spring. This enables the back plate 1 and its side-wall sections to be made of a rigid material. Subsequent to loading the holder, the casing 2 can be lowered, so that its front wall extends vertically. Prior to lowering the casing, however, sufficient paper should be drawn from the roll, to ensure that a length of paper will hang from the holder when the casing is lowered. This length of paper is passed through a T-shaped aperture 10 in a shelf 9. The shelf 9 is preferably formed integrally with the back plate 1 of the holder and extends per-

pendicularly to the plane of said plate. The aperture 10 in the shelf 9 has been taken out through the forward edge of the shelf. This enables a length 11 of the paper roll 8 to be passed in through the part of the aperture forming the stem of the T and then flattened out to practically its full width in the horizontal component of the T-shaped aperture.

The front wall of the casing 2 has firmly mounted on the inner surface thereof a first lip 12 which when the casing 2 is in its lower position terminates at a short distance from a second lip 13 which extends forwardly from the back plate 1 of the holder and beneath the shelf 9. The lips 12, 13 may be provided with tip or edge elements of alternative configuration. In their simplest form the tip or edge elements may consist of rubber strips 14, 15.

The purpose of the rubber strips 14, 15 is to brake the paper web as it moves between the lips 12, 13. This function of the strips has its greatest significance in the aforesaid case of a relatively heavy paper roll being set in motion by pulling the paper web from the roll or holder. The effect of the resultant inertia forces causes the roll to continue to rotate even when the pulling force on the paper web ceases. This results in more paper being unwound from the roll. When the pulling force on the paper web ceases and paper is no longer pulled from the holder, paper which unwinds as a result of free-rotation of the roll will collect in folds on the shelf 9, until the roll comes to a stop. When paper is again taken from the holder, by pulling on the length of paper web hanging beneath the holder, the paper laid in folds on the shelf 9 will be taken first, through the aperture 10, and the roll 4 will not begin to rotate until the paper on the shelf 9 has been withdrawn from the holder.

Figure 5 illustrates an alternative embodiment of the inventive roll holder, which has a back plate 1' which is configured to collect paper unwound from the roll and which thus has a function which corresponds to the function of the shelf 9.

When the roll is placed vertically in the holder, so that the paper web can be withdrawn from the centre of the roll 4', the roll is supported by the sleeve 9. When loading the holder with a paper roll, the outgoing length 11' of the paper web is first passed out through the stem part of the T-shaped aperture 10. This paper length 11' is then fitted between the lips 12, 13. When this method of use is applied, the edges of the paper web will be supported by the shelf 9, quite soon after the inner turns of the roll have been used, with the exception of the region of the three gaps where the paper web crosses the T-shaped opening 10.

The roll holder is advantageously provided with a tear edge 16 by means of which desired lengths of paper can be torn off, irrespective of whether the

paper web is perforated or not. The tear edge 16 is preferably placed in a safe position on the inner surface of the casing front wall, so that there is no danger of inadvertent contact with the fingers or hand, and to that it is ensured that a readily grippable length of paper 11 will hang beneath the lips 12, 13 after tearing off paper from the roll.

As beforementioned, the braking elements on the lips 12, 13 may comprise other devices than the rubber strips 14, 15. For example, when the main parts of the roll holder, i.e. the back plate 1 and the casing 2, are made of a thermoplastic material, the edges of the lips may be thinned down, so that these edges become resilient or springy and therewith afford the desired braking effect.

Alternatively, the web braking elements may have the form of elongated brushes attached to respective lips 12, 13.

In accordance with one variant of the invention, the lips 12, 13 are spaced apart to an extent which enables a hand to be inserted therebetween. Extending parallel with the tips or edges of the lips are two rows of resiliently mounted spheres, each alternate one of which may have a larger diameter than the others. This variant enables a hand to be inserted readily into the holder for the purpose of re-feeding the paper web out of the holder, in the event of the paper web separating inside the holder. This variant is suitable when the casing 2 is capable of being locked.

In accordance with a further alternative, the web braking elements on the tips or edges of the lips may comprise two rows of rollers. These rollers may also be sprung, although the rollers located nearest the edge of the paper web are preferably conical, with the base facing outwards. In this case the greatest braking effect is obtained at the edge of the paper web and perforated paper is torn from the edge and inwards. One advantage with this variant is that a readily grippable length of the paper web will always protrude beneath the rollers at the location of the smallest diameter thereof.

In accordance with another variant of the roll holder, the forwardly located lip 12 is replaced with an element 17 in the form of a suspended cradle 17 having an eccentrically located centre of gravity. Alternatively, the element 17 may be arranged to co-act, under the force of a spring, with the lip 13 extending from the back plate 1 in a manner such that when the element 17 is at rest the edge 18 thereof located nearest the back plate 1 will abut the tip or edge of the lip 13. In one variant the lip 13 is replaced with the element 17 which is spring biased against the lip 12. The cradle-like element 17 may be journalled in the side walls of the casing 2 in a manner which will enable the element to be

moved to one side when needing to draw the end of the paper web out through the aperture 10.

The various web braking elements, including foamed plastic or foam rubber strips, may be configured so that the greatest braking effect occurs at the edges of the material web. This will cause perforated material webs to separate from the edges as the web is drawn out, before the web is separated across the whole of its width. This will ensure that a wedge or slip of paper is always accessible for subsequent withdrawal of material from the roll.

Claims

1. A holder for carrying a thin material web in roll form, having means for securing the holder to a supporting surface, such as a wall, pillar or like structure, and including roll support shafts (8), which are mounted for engagement with the centre cavity of the roll (4) in a manner to support the roll horizontally and to facilitate unwinding of material from the outer periphery of said roll, as well as web braking elements (14,15; 17) which are located downstream of the roll support means as seen in the direction in which the web is drawn from the roll, characterized in that the holder comprises in combination a shelf (9) which has formed therein an aperture (10) and which extends from a back plate (1) of the holder casing at an angle to said plate, the roll (4') being alternatively supported by the shelf in a vertical position and the material web (11') being taken from the central cavity of the roll (4') and through the shelf aperture (10).
2. A holder according to claim 1, characterized in that the roll support shafts (8) are attached to respective resilient side-wall sections (6) which project forwardly from the back plate (1) of the holder casing; and in that said shafts (8) are made of a material which exerts only a small frictional force on the web material defining the central cavity of the roll (4).
3. A holder according to claim 1, characterized in that the roll support shafts (8') are telescopically sprung and fitted to rigid side-wall sections (6').
4. A holder according to claim 1, characterized in that the aperture (10) has an essentially T-shape with an open connection with the forward edge of the shelf (9).
5. A holder according to claim 4, characterized in that the web braking elements (14, 15; 17) are

- located beneath the shelf (9), such that excess web material unwound from a roll supported horizontally on the roll support shafts (8) will collect on the shelf (9).
6. A holder according to any of the preceding claims, characterized in that the web braking elements comprise two mutually co-acting lip edges (14, 15) which are formed of an elastic material and each of which is attached to a respective part of the holder casing.
 7. A holder according to any of claims 1-5, characterized in that the web braking elements comprises mutually opposing brushes.
 8. A holder according to any of claims 1-5, characterized in that the web braking elements comprise two rows of spherical bodies which are biased resiliently towards one another.
 9. A holder according to any of claims 1-5, characterized in that the web braking elements comprise two rows of rollers, of which the outermost roller in each row widens outwardly.
 10. A holder according to claims 1-5, characterized in that the web braking element has the form of a suspended cradle (17) which extends transversely to the path of the material web (11) and the centre of gravity of which is located eccentrically.
 11. A holder according to any of claims 1-5, characterized in that the web braking element comprises a cradle (17) which extends transversely to the path of the material web (11) and which is spring biased in a direction towards either the rear wall or the front wall of the holder casing.
 12. A roller according to any of the preceding claims, characterized in that a tear edge (16) is located in the holder casing between the web braking element and the material web outlet.

Patentansprüche

1. Halter zum Tragen einer dünnen Materialbahn in Rollenform, welcher eine Einrichtung zum Befestigen des Halters an einer Tragfläche, wie einer Wand, einer Stütze oder einer ähnlichen Einrichtung hat, und Rollentragwellen (8) umfaßt, welche derart vorgesehen sind, daß sie in Eingriff mit dem Mittelhohlraum der Rolle (4) derart bringbar sind, daß die Rolle horizontal gehalten wird und das Abspulen des Materials von dem Außenumfang der Rolle erleichtert

wird, sowie Bahnbremselemente (14, 15; 17) umfaßt, welche stromab von der Rollentrageinrichtung in Abzugsrichtung der Bahn von der Rolle gesehen liegen,

- dadurch gekennzeichnet, daß der Halter in Kombination ein Fach (9) aufweist, welches eine darin ausgebildete Öffnung (10) hat und welche sich von einer Rückplatte (1) des Haltergehäuses unter einem Winkel zu dieser Platte erstreckt, die Rolle (4') alternativ durch das Fach in einer vertikalen Position abstützbar ist und die Materialbahn (11) aus dem Mittelhohlraum der Rolle (4') und durch die Fachöffnung (10) entnehmbar ist.

2. Halter nach Anspruch 1, dadurch gekennzeichnet, daß die Rollentragwellen (8) an zugeordneten, federnd nachgiebigen Seitenwandteilen (6) angebracht sind, welche von der Rückplatte (1) des Haltergehäuses nach vorne ragen, und daß die Wellen (8) aus einem Material hergestellt sind, welches nur eine geringfügige Reibungskraft auf das Bahnmateriale ausübt, das den Mittelhohlraum der Rolle (4) bildet.

3. Halter nach Anspruch 1, dadurch gekennzeichnet, daß die Rollentragwellen (8') teleskopartig gefedert und passend zu starren Seitenwandteilen (6') ausgelegt sind.

4. Halter nach Anspruch 1, dadurch gekennzeichnet, daß die Öffnung (10) eine im wesentlichen T-förmige Gestalt mit einer Öffnungsverbindung mit dem vorderen Rand des Fachs (9) hat.

5. Halter nach Anspruch 4, dadurch gekennzeichnet, daß die Bahnbremselemente (14, 15; 17) unterhalb des Fachs (9) derart liegen, daß sich überschüssiges von einer Rolle abgspultes Material, die an den Rollentragwellen (8) horizontal gelagert ist, auf dem Fach (9) sammeln läßt.

6. Halter nach einem der vorangehenden Ansprüche, dadurch gekennzeichnet, daß die Bahnbremselemente zwei wechselweise zusammenarbeitende Lippenkanten (14, 15) aufweisen, welche aus einem elastischen Material ausgebildet sind und die jeweils an einem zugeordneten Teil des Haltergehäuses angebracht sind.

7. Halter nach einem der Ansprüche 1 bis 5, dadurch gekennzeichnet, daß die Bahnbremselemente wechselweise gegenüberliegend angeordnete Bürsten aufweisen.

8. Halter nach einem der Ansprüche 1 bis 5, **dadurch gekennzeichnet**, daß die Bahnbremselemente zwei Reihen von sphärischen Körpern aufweisen, welche aufeinanderzu federnd vorbelastet sind.

5

9. Halter nach einem der Ansprüche 1 bis 5, **dadurch gekennzeichnet**, daß die Bahnbremselemente zwei Reihen von Rollen aufweisen, von denen sich die am weitesten außen liegende Rolle in jeder Reihe in Richtung nach außen erweitert.

10

10. Halter nach einem der Ansprüche 1 bis 5, **dadurch gekennzeichnet**, daß das Bahnbremselement die Form eines schwebend gelagerten, wiegenförmigen Teils (17) hat, welches sich in Querrichtung zu der Bewegungsbahn der Materialbahn (11) erstreckt und dessen Schwerkraftsmittelpunkt exzentrisch ist.

15

20

11. Halter nach einem der Ansprüche 1 bis 5, **dadurch gekennzeichnet**, daß das Bahnbremselement ein wiegenförmiges Teil (17) aufweist, welches sich in Querrichtung zu der Bewegungsbahn der Materialbahn (11) erstreckt, und welches in einer Richtung entweder auf die Rückwand oder die Vorderwand des Haltergehäuses federvorbelastet ist.

25

30

12. Rolle nach einem der vorangehenden Ansprüche, **dadurch gekennzeichnet**, daß eine Reißkante (16) im Haltergehäuse zwischen dem Bahnbremselement und dem Materialbahnauslaß angeordnet ist.

35

Revendications

1. Support pour porter une bande de produit mince en forme de rouleau, comprenant des moyens pour fixer le support sur une surface de support telle qu'un mur, un pilier ou une surface similaire, et comprenant des arbres supports (8) du rouleau montés de manière à entrer en engagement avec la cavité centrale du rouleau (4) d'une manière à supporter le rouleau horizontalement et à faciliter le déroulement du produit de la périphérie extérieure du dit rouleau, ainsi que des éléments (14, 15; 17) de freinage de la bande, disposés en aval des moyens supports du rouleau, dans le sens dans lequel la bande est tirée du rouleau, caractérisé en ce que le support comporte, en combinaison, un plateau (9) dans lequel est formée une ouverture (10) et qui s'étend depuis la plaque dorsale (1) du carter support, à un angle par rapport à ladite plaque, le rouleau (4') pouvant aussi être supporté sur le plateau

40

45

50

55

en position verticale, et la bande de produit (11') étant dévidée à partir de la cavité centrale du rouleau (4') et à travers l'ouverture (10) du plateau.

2. Support selon la revendication 1, caractérisé en ce que les arbres supports (8) sont fixés sur des sections élastiques respectives (6) de paroi latérale qui se projettent vers l'avant à partir de la plaque dorsale (1) du carter du support; et en ce que lesdits arbres (8) sont réalisés en une matière qui n'exerce qu'une faible force de frottement sur la bande de produit définissant la cavité centrale du rouleau (4).

3. Support selon la revendication 1, caractérisé en ce que les arbres supports (8') du rouleau sont des éléments télescopiques à ressorts et sont fixés sur des sections de parois latérales rigides (6').

4. Support selon la revendication 1, caractérisé en ce que l'ouverture (10) présente essentiellement la forme d'un T, l'ouverture rejoignant le bord avant du plateau (9).

5. Support selon la revendication 4, caractérisé en ce que les éléments de freinage (14, 15; 17) de la bande sont situés en dessous du plateau (9), de manière telle que du produit de la bande, qui se déroule d'un rouleau maintenu dans le sens horizontal sur les arbres supports (8), s'entasse sur le plateau (9).

6. Support selon l'une quelconque des revendications précédentes, caractérisé en ce que les éléments de freinage de la bande comprennent deux bords de lèvres (14, 15) coopérant l'un avec l'autre, qui sont formés en une matière élastique, et dont chacun est rattaché à une partie respective du carter du support.

7. Support selon l'une quelconque des revendications 1 à 5, caractérisé en ce que les éléments de freinage de la bande comprennent des brosses opposées l'une à l'autre.

8. Support selon l'une quelconque des revendications 1 à 5, caractérisé en ce que les éléments de freinage de la bande comprennent deux rangées de corps sphériques forcés élastiquement les uns contre les autres.

9. Support selon l'une quelconque des revendications 1 à 5, caractérisé en ce que les éléments de freinage de la bande comprennent deux rangées de rouleaux, le rouleau extérieur de

chaque rangée s'élargissant vers l'extérieur.

10. Support selon l'une quelconque des revendications 1 à 5, caractérisé en ce que l'élément de freinage de la bande présente la forme d'un berceau suspendu (17) s'étendant transversalement au chemin de la bande de produit (11), et dont le centre de gravité est excentré. 5
11. Support selon l'une quelconque des revendications 1 à 5, caractérisé en ce que l'élément de freinage de la bande comprend un berceau (17) s'étendant transversalement au chemin de la bande de produit (11), et qui est rappelé par ressort dans un sens dirigé soit vers la paroi arrière, soit vers la paroi avant du carter du support. 10 15
12. Support selon l'une quelconque des revendications précédentes, caractérisé en ce qu'un bord de découpe (16) est placé dans le carter du support, entre l'élément de freinage de la bande et la sortie de la bande de produit. 20
